

The Contact Lens Impact on Quality of Life (CLIQ) Questionnaire: Development and Validation

Konrad Pesudovs,¹ Estibaliz Garamendi,² and David B. Elliott²

PURPOSE. To develop and validate a questionnaire for the measurement of the impact of contact lenses on quality of life (QoL): The Contact Lens Impact on Quality of Life (CLIQ) Questionnaire.

METHODS. The questionnaire was developed and validated using conventional methods and Rasch analysis to assure content validity, repeatability, construct validity, and low respondent burden. Item identification and selection (647 items) were performed with an extensive literature review, professional advice, and lay focus groups. Item reduction used focus groups and data obtained from 161 subjects completing a 90-item pilot questionnaire. Validity and reliability, from data of 128 additional subjects, were assessed using Rasch analysis, intraclass correlation coefficient, and Bland-Altman limits of agreement.

RESULTS. A 28-item CLIQ Questionnaire was developed and shown to have good validity and reliability by Rasch analysis statistics: real person separation, 2.02; model person separation, 2.17; reliability, 0.80; root mean square measurement error, 2.73; mean square \pm SD infit, 1.01 ± 0.18 ; outfit, 1.01 ± 0.19 . The items (mean score, 49.8 ± 4.9) were well targeted to the subjects (mean score, 51.2 ± 6.2) with a mean difference of 1.35 (scale range, 0–100) units. Test-retest intraclass correlation coefficient (0.86) and coefficient of repeatability (± 8.00 units) demonstrated good repeatability.

CONCLUSIONS. Rasch analysis and standard psychometric analyses demonstrated that the 28-item CLIQ Questionnaire is a valid and reliable measure of QoL in contact lens wearers. A scoring algorithm is provided for CLIQ Questionnaire users to convert raw scores into the Rasch analysis-derived linear person measures. (*Invest Ophthalmol Vis Sci.* 2006;47:2789–2796) DOI:10.1167/iops.05-0933

The effect of refractive error and its correction has traditionally been characterized by clinical measures such as visual acuity or contrast sensitivity. While these measures provide important information, they give little indication of the impact of refractive error or its correction on the person as a whole. This shortfall has been addressed by using questionnaires for the assessment of quality of life (QoL), which has now become a standard approach for assessing patient-centered outcomes in

healthcare.^{1–3} The impact of refractive corrections can now be assessed using several QoL instruments that go beyond traditional clinical measures.^{4–9}

Changes in QoL of patients wearing contact lenses have been reported with conventionally validated questionnaires.^{10–17} However, several of these questionnaires are restricted to dry eye symptoms^{10,13,14} and another to psychological issues.¹⁵ In addition, the Refractive Status and Vision Profile (RSVP) and National Eye Institute Visual Function Questionnaire (NEI-VFQ) have been shown to be insensitive to QoL matters relevant to people who wear contact lenses.^{11,12} The National Eye Institute Refractive Error Quality of Life (NEI-RQL) questionnaire, although not developed specifically for contact lens wearers, has been reported to discriminate between different modes of contact lens wear.^{16,17} In other studies that report QoL issues related to contact lens wearers, informal, nonvalidated questionnaires were used.^{18–24}

Considerations in selecting a QoL instrument should include its reliability and validity. Many currently available refractive-error-related QoL instruments, including the RSVP, NEI-VFQ, and NEI-RQL, use traditional Likert scoring,²⁵ in which patients' response scores for a selected set of items are summed to derive the overall score. Likert scoring assumes that the value of each item represents equal difficulty and therefore scores them equally. In addition, the ordinal integer response scale used for each item assumes uniform changes between response categories. For example, in a Likert-scaled vision disability instrument such as the Activities of Daily Vision Scale (ADVS),²⁶ a response of "a little difficulty" (score of 4) is used to represent twice the level of ability as "extreme difficulty" (score of 2) which is similarly two times as good as "unable to perform the activity due to vision" (score of 1) for all items. This appears illogical, and Rasch analysis has been used to confirm that specific response-category calibrations are essential for providing a linear scale.²⁷ Similarly, Likert scales assume that all items are of equal difficulty. For example, with the ADVS instrument an answer of "a little difficulty" to the question regarding visual difficulties driving at night scores the same as the "a little difficulty" with driving during the day. Again, this assumption is illogical. Rasch analysis has been used to confirm that subjects report that driving at night is a more difficult task than driving during the day and Rasch analysis can provide an appropriate weighting for each item.²⁷ Uncorrected, these problems cause discontinuities in the scale and nonlinear measurement, which occurs for instance with the NEI-RQL and the RSVP.²⁸ We have developed a refractive-error-related questionnaire using Rasch analysis to overcome these problems and have created a truly linear measure of refractive-error-related QoL: the Quality of Life Impact of Refractive Correction Questionnaire (QIRC).^{8,29,30} QIRC was developed for spectacle wearers, contact lens wearers and refractive surgery patients. Although QIRC may be a good instrument to measure QoL for contact lens wearers, we hypothesize that if a questionnaire were developed specifically for contact lens wearers, it may necessitate a slightly different content to be more sensitive to some issues specific to contact lens wear.

The purpose of this study was to develop and validate a questionnaire, using Rasch analysis, for the measurement of

the impact of contact lenses on QoL: The Contact Lens Impact on Quality of Life (CLIQ) questionnaire. The questionnaire was targeted at adults needing refractive correction who did not have other ophthalmic problems, but was confined to the prepresbyopic population. Most contact lens wearers are prepresbyopes,⁵¹ and presbyopes are likely to encounter different problems than prepresbyopes, related to the use of multifocal contact lenses, monovision (a contact lens for distance vision in one eye and near vision in the other) or the need for reading glasses in addition to distance vision contact lenses.

METHODS

The CLIQ Questionnaire was developed according to standard procedures,³ augmented by the item reduction and scoring applications of Rasch analysis.^{32,33} Rasch analysis was performed using Winsteps (ver. 3.35), applying the Andrich rating scale model with joint maximum-likelihood estimation.³² One model was used for each question type (five), but rating scale models that behaved in the same way were combined. The Rasch model does not assume values for response categories (e.g., 1, 2, 3 . . .), but rather that all categories are on the same underlying latent variable. The Rasch model gives the probability of selecting a particular response category in terms of the interaction between "response severity" and subject measure through an iterative logistic process.³⁴ The resultant response scale calibrations and person measures are expressed in log-odd units (natural logarithm of an odds ratio), or logits, positioned along a hierarchical scale with logits of greater magnitude representing increasing QoL.³⁴ By definition, this scale is linear.

Domain and Item Identification and Selection

Domains and items thought likely to be influenced by refractive correction were collected from six sources: a search of the general QoL literature,^{35–39} a search of the vision-related QoL literature,^{40–42} including that relating to refractive error correction,^{4,43–47} retrospective analysis of case records at the University of Bradford Eye Clinic, invited responses from 63 practitioners and allied health workers in the fields of optometry, ophthalmology, contact lens practice and psychology, and focus groups (lay people and professionals in the fields mentioned); 647 items were identified. These could be categorized into domains of well-being ($n = 192$; of these 108 were associated with psychological well-being and 84 with social well-being), functional vision ($n = 176$), symptoms ($n = 97$), convenience issues ($n = 85$), economic issues ($n = 54$), cognitive issues ($n = 24$), and health concerns ($n = 19$). Question format was kept as regular as possible, but different content areas required different question syntax. Two styles of questions were chosen: severity assessment (e.g., How much difficulty do you have. . . ?) and incidence (e.g., During the past month, how often have you experienced. . . ?). A five-category response scale was chosen as it has been shown to be more useful and easier to complete compared with four- and seven-category response scales and a visual analogue scale.⁴⁸ Suitably spaced response labels were selected from the research literature.⁴⁹ Each different question structure and response scale was allocated to an Andrich rating scale model in the Rasch analysis.

The original 647 items were reduced to 115 by a professional focus group. In this process, many items were merged for having similar content (e.g., reading small print, reading medicine bottles). Others were discarded for not being relevant to most people (e.g., ability to cross-stitch). These 115 items were formatted into a self-administration questionnaire for further discussion by lay focus groups. They recommended discarding a further 25 items and numerous minor rewordings of instructions and questions to assist comprehension. Advice was also taken from the lay focus groups on the wording of the instructions. The 90 items for the pilot questionnaire were distributed among the domains of convenience issues ($n = 20$), functional vision ($n = 19$),

well-being ($n = 16$), symptoms ($n = 16$), health concerns ($n = 8$), economic issues ($n = 8$), and cognitive issues ($n = 3$).

The 90-Item Pilot Questionnaire

The study was designed so that the final questionnaire would be relevant to the population of the United Kingdom. Thus, it was administered in 15 centers throughout the country, chosen to provide data from rural and urban areas and with a good geographical spread. Subjects were chosen on a consecutive-patient basis under the constraints of time inherent in a commercial practice. The success of recruiting a representative population was established through comparison of demographic information regarding gender, ethnicity and socioeconomic classification against U.K. national data.⁵⁰ Inclusion criteria were age between 16 to 35 years (adult prepresbyopic age) and the use of contact lenses. Exclusion criteria were previous ocular surgery, eye disease, neurologic disease, systemic disease, or medication that may alter visual function and inability to read or understand the questionnaire. Informed consent was obtained from all subjects after the nature of the study had been fully explained. The tenets of the Declaration of Helsinki were observed, and the study gained approval from the university ethics committee. The 90-item pilot questionnaire was completed by self-administration by 161 subjects across optometry and contact lens practice settings. Five questionnaires were discarded due to the absence of demographic data or greater than 33% missing item responses. Rasch analysis was used to identify unusual response patterns. The Rasch model fit statistics infit and outfit mean square were used to monitor the compatibility of the data with the model. Nineteen subjects gave poor Rasch fit statistics (both outfit and infit mean square > 1.40) indicating that their responses were very different from most of the subjects, and so the authors reviewed their questionnaires. Twelve of these were retained, as they appeared to provide reliable responses in a pattern different from that of the majority. The seven questionnaires that were discarded either contained the same category response for (typically) the last three pages of the questionnaire (these pages contained questions with reversed scales—typically a good QoL would score 1, but for some questions a good QoL scored 5—so that a respondent who marked 1 for all questions on a page suggested responding without reading the questions and therefore unreliable data). This left a final n of 149 (mean age, 26.6 ± 4.7 years). Rasch analysis was then used for item reduction.

Assessment of the Validity and Reliability of the 28-Item CLIQ

The 28-item CLIQ Questionnaire (Table 1) was again administered in several settings across the United Kingdom. Questions 21 to 28 regarding feelings of well-being were asked in relation to the subject's refractive correction, in that the foreword to the questions included the following text: "We are now interested in the effect that your contact lenses have had on the way you have been feeling. The effect on your feelings may be obvious (e.g., you may feel that you look better in your contact lenses) or it may be indirect (e.g., you may feel more confident wearing contact lenses because you feel that you look better)." One hundred forty-two questionnaires were returned. Seven questionnaires were discarded due to absent demographic data or greater than 33% missing item responses. Rasch outfit statistics identified 21 possible inconsistent responders and after review; 14 were retained. This left 128 questionnaires. The validity of the CLIQ data was assessed using Rasch analysis.

Demographic Data

Ethnicity classification was sourced from the Compendia and Reference section of the National Statistics Web site.⁵⁰ Socioeconomic classification for the pilot questionnaire was assigned from residential postcode data as the Index of Multiple Deprivation, which is a logarithm comparing each location with the highest socioeconomic status location in Britain (a lower score indicates a higher classification), as sourced from the National Statistics Web site.⁵⁰ Although this is a

TABLE 1. The 28 Items Included in the CLIQ Questionnaire, with Rasch Fit Statistics and Item Calibration

Item Description	Infit Mean Square (z STD)	Outfit Mean Square (z STD)	Item Calibration (SE)
1 How much difficulty do you have driving in glare conditions with your contact lenses?	1.05 (0.5)	1.13 (1.1)	44.6 (1.2)
2 How much difficulty do you have performing any activity due to dim lighting with your contact lenses?	0.88 (−1.2)	0.97 (−0.2)	41.5 (1.2)
3 During the past month, how often have you experienced your vision changing/fluctuating throughout the day, either improving or deteriorating with your contact lenses?	1.10 (0.9)	1.19 (1.4)	42.1 (1.2)
4 During the past month, how often have you experienced focusing difficulties with your contact lenses?	0.88 (−1.1)	0.90 (−0.8)	40.9 (1.2)
5 During the past month, how often have you experienced your eyes feeling tired or strained with your contact lenses?	0.91 (−1.0)	0.94 (−0.6)	51.7 (1.1)
6 During the past month, how often have you experienced red/painful/itchy/burning/sore/uncomfortable/gritty or dry eyes with your contact lenses?	1.06 (0.6)	1.06 (0.6)	44.4 (1.1)
7 How much trouble is the routine care of your contact lenses (e.g., cleaning, using eye drops)?	0.96 (−0.3)	0.88 (−0.9)	40.0 (1.3)
8 How much trouble is having to think about contact lenses before doing things (traveling, sport, going swimming)?	0.89 (−1.2)	0.88 (−1.3)	53.3 (1.1)
9 How much trouble is having to carry additional cleaning supplies for contact lenses when traveling?	1.17 (1.8)	1.16 (1.6)	49.6 (1.1)
10 How much trouble is having to insert things into your eyes (e.g., contact lens, eye drops)?	0.93 (−0.6)	0.95 (−0.4)	40.0 (1.2)
11 How much trouble is being unable to have good, comfortable vision all day with your contact lenses?	1.09 (0.9)	1.03 (0.3)	42.1 (1.2)
12 How concerned are you about the initial and ongoing cost of buying your current contact lenses?	1.01 (0.1)	1.00 (0.0)	53.3 (1.1)
13 How concerned are you about the cost of your next contact lenses?	0.90 (−1.2)	0.88 (−1.4)	51.6 (1.1)
14 How concerned are you about the cost of unscheduled maintenance of your contact lenses: breakage, loss, running out of supplies?	0.83 (−2.0)	0.88 (−1.3)	48.5 (1.1)
15 How concerned are you about having to rely increasingly on your contact lenses since you started to wear them?	1.09 (1.0)	1.11 (1.1)	52.4 (1.1)
16 How concerned are you about your vision being not as good as it could be with your contact lenses?	1.03 (0.4)	1.02 (0.3)	48.6 (1.1)
17 How concerned are you about medical complications from your contact lenses?	1.02 (0.2)	0.98 (−0.2)	43.0 (1.2)
18 How concerned are you about eye allergies/infections?	0.92 (−0.9)	0.93 (−0.7)	49.5 (1.1)
19 How concerned are you about falling asleep in your contact lenses?	1.10 (1.1)	1.10 (1.0)	50.8 (1.1)
20 How concerned are you about eye protection from ultraviolet (UV) radiation?	1.17 (1.8)	1.17 (1.7)	48.4 (1.1)
21 During the past month, how much of the time have you felt that you have looked your best when wearing contact lenses?	0.86 (−1.5)	0.85 (−1.5)	54.8 (0.9)
22 During the past month, how much of the time have you felt happy with your facial appearance when wearing contact lenses?	1.00 (0.0)	1.00 (0.0)	54.1 (0.9)
23 During the past month, how much of the time have you felt that others see you the way you would like them to when wearing contact lenses (e.g., intelligent, sophisticated, successful, cool)?	1.04 (0.4)	1.05 (0.5)	56.9 (1.0)
24 During the past month, how much of the time have you felt complimented/flattered when wearing contact lenses?	1.22 (1.48)	1.18 (1.45)	63.0 (1.1)
25 During the past month, how much of the time have you felt confident when wearing contact lenses?	0.84 (−1.7)	0.84 (−1.6)	51.3 (0.9)
26 During the past month, how much of the time have you felt happy when wearing contact lenses?	0.73 (−2.8)	0.74 (−2.6)	47.3 (0.9)
27 During the past month, how much of the time have you felt able to do the things you want to do when wearing contact lenses?	1.17 (1.5)	1.19 (1.7)	47.2 (0.9)
28 During the past month, how much of the time have you felt eager to try new things when wearing contact lenses?	1.12 (1.2)	1.11 (1.1)	51.5 (0.9)

recognized method, we were concerned about the accuracy of post-code-based assignment with a small sample such as $n = 149$. Therefore, we replaced this method for the second phase of the study with a classification assigned from self-report of occupation of the primary income earner in the household.⁵¹

RESULTS

The 90-Item Questionnaire

The pilot questionnaire was administered to 149 contact lens wearers. Ages ranged from 16 to 34 (mean, 26.6 ± 4.7). The socioeconomic status, as described by the Index of Multiple Deprivation was 1.31 ± 0.20 , slightly less affluent than the U.K.

national average (1.23 ± 0.31).⁵⁰ Approximately 67% of subjects were female and the ethnicity distribution (approximately 92% white) across the entire cohort was representative of the total U.K. population.⁵⁰ Although the gender distribution shows a larger proportion of females compared with the total U.K. population, it is representative of the U.K. population seeking eye care.⁵²

Figure 1 shows a subject QoL against item difficulty map established by Rasch analysis for the original 90-item CLIQ Questionnaire. Subjects (each # on the left represents three subjects) appear in ascending order of QoL from the bottom of the figure to the top. Items appear on the right represented by item numbers, with a decimal representing the response scale

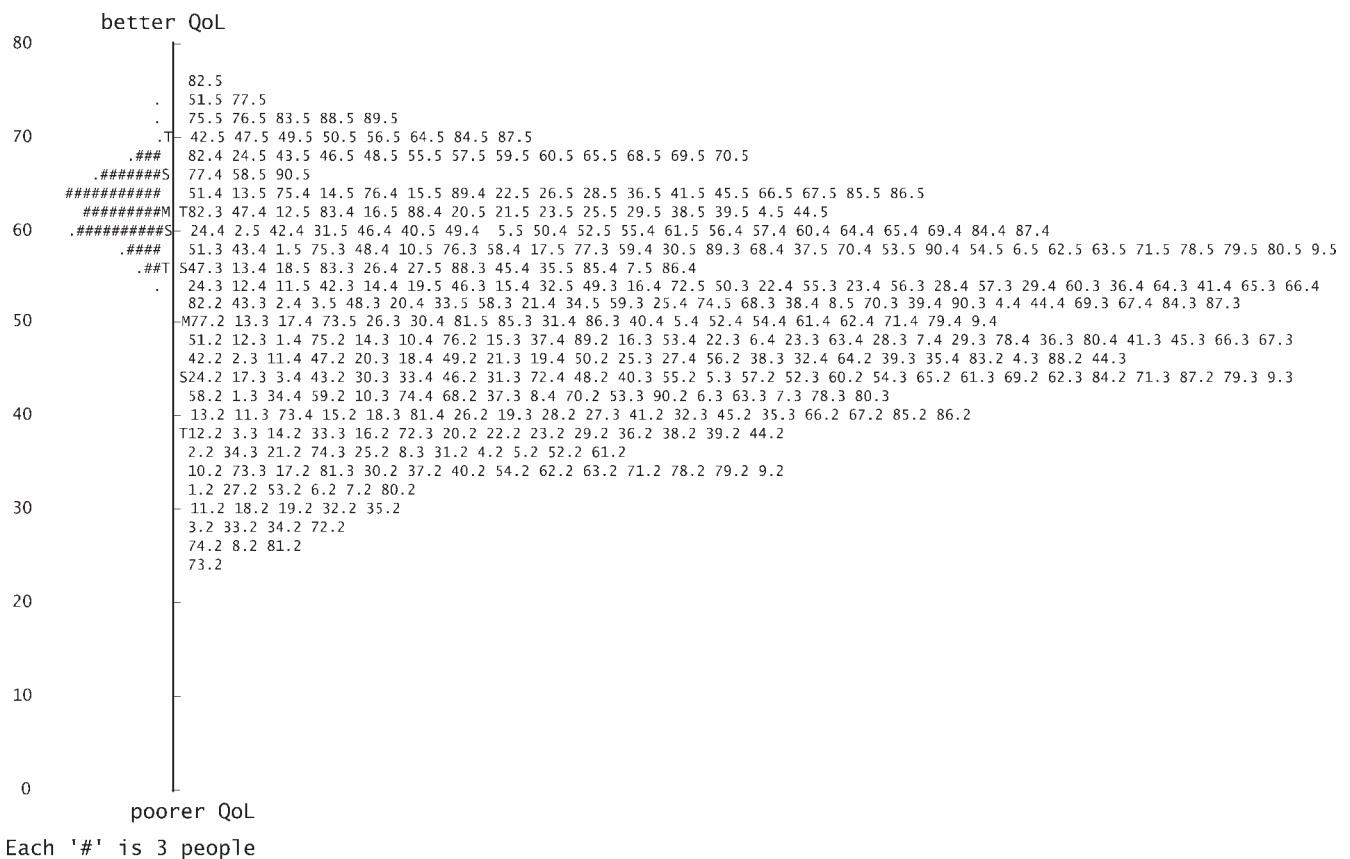

FIGURE 1. Person-item map for the 90-item pilot CLIQ with the boundary for each response category for each item shown on the *right*. On the *left* of the *dashed line* are the subjects, represented by # (each corresponds to three subjects). Subjects with poorer QoL are near the *bottom* of the diagram, and subjects with better QoL are near the *top*. Items that less positively affect QoL in people with contact lens refractive correction are near the *bottom* of the diagram, and items that positively affect QoL are near the *top*. The scale is in units (0-100), and abbreviations on the diagram are M = mean, S = 1 SD from the mean, and T = 2 SDs from the mean.

boundary. With a five-category scale, there are four boundaries between categories, so that each item is represented in the figure by four points (Fig. 2). Boundaries occur at the point on the scale where the response most likely to be selected

FIGURE 2. Category probability curves for a well-being item illustrating the range of the scale over which each of the five categories is most likely to be chosen. Boundaries occur at points along the scale where the category most likely to be chosen changes from one to the next.

changes from one category to the next, appearing in ascending order of severity of impact of contact lenses on QoL, from the bottom of the figure to the top. In Figure 1, both subjects and items appear along the same scale, which is a linear transformation of the Rasch logit scale to fit a 0 to 100 scale (Winsteps Umean = 50.39, Uscale = 6.76). For this sample, many items, especially visual functioning items (items 1-19) have little impact on the QoL of the contact lens wearers. This result is shown as the subjects located higher and item numbers located lower in the Rasch map and illustrates inadequate targeting of item severity to subject QoL issues related to contact lens refractive error correction. If the items were well targeted to the subjects, the means of the two distributions, denoted in Figure 1 by M, would be close to each other. We attempted to improve targeting of items to subjects through response scale reduction and item reduction.

The five different types of question wording were analyzed with five different rating scale models. Four of these models performed the same, in that the scale widths of the categories were very similar. Only the model for the well-being domain performed differently. However, for all five models, the five response categories on the CLIQ Questionnaire were not all used with the same frequency. The extreme or equivalent response category (one response category) was not used for 48 of the 90 items by any of the subjects. In addition, responses in this end category were few and ranged from 0.68% to 26.5%, of which only one item had 26.5% of the responses and all the remaining items included lower than 15% of the responses. To improve the underutilization of the end category the two

highest rating categories “extreme” (category 1) and “quite a lot” (category 2) or their equivalent could be combined to improve targeting of items to subject QoL.^{33,53} This change resulted in a reduction in the mean difference between item difficulty and subject QoL from 12.13 to 9.78 units and a slight increase in person separation from 2.87 to 2.89. There was still a significant mismatch of item targeting to subjects. The combined response category was still underutilized for many items, although not for the well-being items. For the 74 non-well-being items, the combined end category was still empty for 14 items and 59 items had less than 15% of the responses. Therefore, it was decided to combine the response category “a moderate amount” with the already combined “quite a lot” and “extreme.” This further reduced the difference between the mean value for the subjects and the mean value of the items to 8.29 units. Shortening the response scale did not significantly alter person separation (five-category = 2.87, four-category = 2.89, three-category with four-category for well-being items = 2.91). Because four of the response scale models performed similarly (category widths, 4.4, 3.5, 3.8, and 3.3), it was decided to combine these into one model. Therefore, a two-rating scale Rasch analysis was used, with the advantage that item fit statistics then become a powerful indicator of internal consistency that facilitates decision-making during item reduction.

Although the combined-response category improved the difference between item and subject mean values, there were still several items providing relatively little information. Rasch analysis was then used to remove poorly fitting items from the questionnaire, which were removed one at a time, as item removal changes fit statistics. This improved the fit of some items that initially had high infit-outfit values and reduced the mean difference between item difficulty and subject QoL. The criteria used for item removal were^{8,27}:

1. Infit mean square outside 0.80 to 1.20.
2. Outfit mean square outside 0.70 to 1.30.
3. Item with mean farthest from the subject mean.
4. A high proportion of missing data (greater than 50%).
5. Ceiling effect: a high proportion in item end-response category (greater than 50%).
6. Skew and kurtosis outside -2.00 to $+2.00$.

The item with the highest number of candidate criteria, ordered by priority, was removed first. If removal of an item with high or low infit-outfit values considerably decreased person separation (<2.0), that item was retained.⁵⁴ Person separation is an indicator of the ability (precision) of the instrument to differentiate between different persons' QoL. Person separation is expressed as the ratio of the adjusted SD to the root mean square error. A person separation of 2.0 or more is indicative that subjects are significantly different in QoL across the measurement distribution.⁵³ This iterative process finally resulted in a 28-item questionnaire with a real person separation of 2.04 and mean difference of 2.34 units (Fig. 3). Reducing the number of items further led to decreased person separation. This again was fit to a 0 to 100 scale (Winsteps Umean = 48.66, Uscale = 9.01).

Assessment of the Validity and Reliability of the 28-Item CLIQ

The shortened version was completed by an additional 128 contact lens wearers. The respondents included 67% female patients with a mean \pm SD age of 27.7 ± 5.4 years (range, 17–35 years). Socioeconomic status and ethnicity (93% white) were similar to that the total U.K. population,^{50,51} and gender was similar to the U.K. population seeking eye-care.⁵² The items (mean score, 49.8 ± 4.9) were well targeted to the

Each '#' is 2 people

FIGURE 3. Person-item map for the 28 item final CLIQ with the boundary for each response category for each item shown on the *right*. On the *left* of the *dashed line* are the subjects, represented by # (each corresponding to three persons). The sample population shows excellent targeting of items to subjects.

subjects (mean score, 51.2 ± 6.2) with a mean difference of 1.35 (scale range, 0–100) units. The time taken to complete CLIQ was measured for 15 subjects, with a mean value of 9 minutes (range, 6–12 minutes).

Rasch analysis provided valid model statistics (real person separation, 2.02; real reliability, 0.80; model person separation, 2.17; model reliability, 0.82; root mean square measurement error, 2.73; mean square \pm SD infit, 1.01 ± 0.18 ; outfit, 1.01 ± 0.19) and fit statistics showed that all items fit within a range of infit from 0.62 to 1.36 and of outfit from 0.63 to 1.37. Thus, the variance within items extends from 38% (for infit) and 37% (for outfit) less than the expected to 36% (for infit) and 37% (for outfit) more than the expected. These figures are larger than those in Table 1, as these data are from another sample of subjects. These findings suggest all items measure a unitary concept, without redundancy. A sample ($n = 45$) of subjects were retested, and reproducibility was found to be good: intraclass correlation coefficient = 0.86 and coefficient of repeatability = ± 8.00 units.^{55,56}

Scoring of the CLIQ Questionnaire

Other investigators wishing to use the CLIQ Questionnaire can use our validation data to convert raw scores into Rasch person measures. Each question has a five-category response scale, but

items 1 to 20 are collapsed to three categories and items 21 to 28 are collapsed to four categories. Also, items 1 to 20 (lower score is better) have polarity opposite that of items 21 to 28 (higher scores are better), so items 1 to 20 are reversed in polarity to give an overall higher score for better QoL. Therefore, for categories (1, 2, 3, 4, 5) assign (5, 4, 3, 3, 3) to the first 20 items and scores (2, 2, 3, 4, 5) to items 21 to 28. The average of these 28 items gives the CLIQ raw score. The score is related to the CLIQ Rasch person measure as illustrated in Figure 4. The relationship is double asymptotic, because the average raw rating has a floor and a ceiling. The relationship can be described by the double-asymptotic nonlinear regression⁵⁷: $\text{CLIQ}_{\text{person measure}} = 34.41 \times \log(\text{CLIQ}_{\text{raw score}}/5 - \text{CLIQ}_{\text{raw score}}) + 26.69$.

DISCUSSION

The CLIQ Questionnaire was rigorously developed using both conventional techniques and Rasch analysis to assure good content validity, internal consistency, and a low respondent burden.

According to the assessments suggested by de Boer et al.,⁵⁸ the psychometric properties of CLIQ were shown to be of high quality. Item selection included a thorough literature review and the input of patients, clinicians, and focus groups. Item reduction was of high quality, as items that measured something different to the overall scale or redundant items were removed using infit and outfit Rasch statistics and items with ceiling and floor effects were also removed. Items were reduced from 647 to 28. Respondent burden is chiefly driven by the number of items, and so reducing the number of items while retaining good measurement properties is a key issue in questionnaire development.⁵⁴ The respondent burden on the patient was low, with an average completion time for the 28-item CLIQ being less than 11 minutes in nearly all cases.

The item reduction phase highlights an advantage of Rasch analysis beyond the obvious importance that it provides a quantitative score that is a valid linear measurement. We started with items in seven domains and used five rating scale models for these domains. However, only the well-being rating scale model performed differently from the other four

models, and so a two-rating scale analysis could be performed. This method improves the assessment of internal consistency that is attainable using Rasch fit statistics, and allowed us to reduce items while maintaining internal consistency and relevance to the population. The pilot questionnaire, although influenced by suggestions from lay people, was principally clinician-driven and contained many questions relating to functional vision (21%). However, Rasch analysis clearly indicated that subjects with corrected refractive error wearing contact lenses have relatively few problems with functional vision (Fig. 1), so that many of these questions were not required, with only two items being retained in the 28-item CLIQ. If they had been left in, CLIQ would have targeted the population poorly. This may be why other vision-related QoL instruments that principally contain functional vision items, such as the RSVP (23% items in the functional vision domain), lack sensitivity in subjects with different modes of contact lens wear.¹² The results reported in the present study show that subjects at large have few problems with visual function that are not corrected, and issues such as symptoms, convenience, cost, health concerns, and appearance determine the influence of contact lens refractive error correction on QoL (Table 1). This demonstrates the importance of using Rasch analysis in the development of a questionnaire to ensure good internal consistency and targeting of items to people. Rasch analysis could be applied to existing questionnaires to gain its benefits in terms of scoring, but this approach may expose inadequacies in a conventionally developed questionnaire in terms of internal consistency and item targeting.^{27,28} This is indeed the case for one refractive error correction related QoL questionnaire, the RSVP,²⁸ but whether any problems exist with the NEI-RQL remains to be tested.

Removal of poorly fitting data was a thorough procedure. We deliberately worded several questions to allow reversal of the scale direction to catch careless responders. Rasch analysis provides a powerful test for inconsistent data through the outfit statistic. Thus, we were able to reduce the influence of poor data on the dataset.

As hypothesized, the content of CLIQ is different from QIRC which, contrastingly, was developed to suit spectacle wearers, contact lens wearers, and people undergoing refractive surgery.²⁹ Sixteen of the 20 items in QIRC are also included in CLIQ.⁸ Therefore, there are 12 items included in CLIQ that are not found in QIRC. This difference in content is due to developing CLIQ on contact lens patients only and thereby including only content relevant to that population. Although QIRC can be used on contact lens patients, we contend that CLIQ has better content validity for contact lens patients, and should be used in preference to QIRC (or any other questionnaire not solely developed for contact lens wearers) wherever possible. CLIQ should suit all modes of contact lens wear as the test populations did not exclude any lens types, but since they were unselected, the populations were dominated by soft disposable lens wearers, but did include all types. Differences in QoL between different types of contact lenses remain to be demonstrated. This is a key purpose for developing the CLIQ Questionnaire.

The limitations of CLIQ include that it has been developed only for the prepresbyopic population, although this represents most contact lens wearers.³¹ Nevertheless, CLIQ could still be used in presbyopes as long as it is interpreted that presbyopia-specific issues are not addressed. Another limitation is that CLIQ has a small sample population for test-retest reliability analysis.³ Additional testing is needed to assess the remaining psychometric properties required to assess vision-related QoL instruments fully, such as construct validity, responsiveness, and interpretability, as suggested by de Boer et al.⁵⁸

FIGURE 4. Scatterplot of the person measure estimated from Rasch analysis versus the average rating for each person across items. These data can be fit with a double-asymptotic nonlinear equation: $\text{CLIQ}_{\text{person measure}} = 34.41 \times \log(\text{CLIQ}_{\text{raw score}}/5 - \text{CLIQ}_{\text{raw score}}) + 26.69$.

In conclusion, we present the CLIQ Questionnaire (available online at <http://www.iovs.org/cgi/content/full/47/7/2789/DC1>). This is a 28-item questionnaire reporting a single-valued score of QoL in contact lens wearers. It has several advantages over existing instruments: demonstrated with Rasch analysis that all items measure a single content area, and scaled using Rasch analysis to be a truly linear measurement of QoL where items are weighted for their impact on QoL.

Acknowledgments

The authors thank Michael Stevens, Helen Scott, Jenny Burr, Simon Gelsthorpe, and Alison Torn for assistance with professional and lay focus groups, and Mike Linacre for help with various aspects of Rasch analysis.
